The whole Cosmosis system

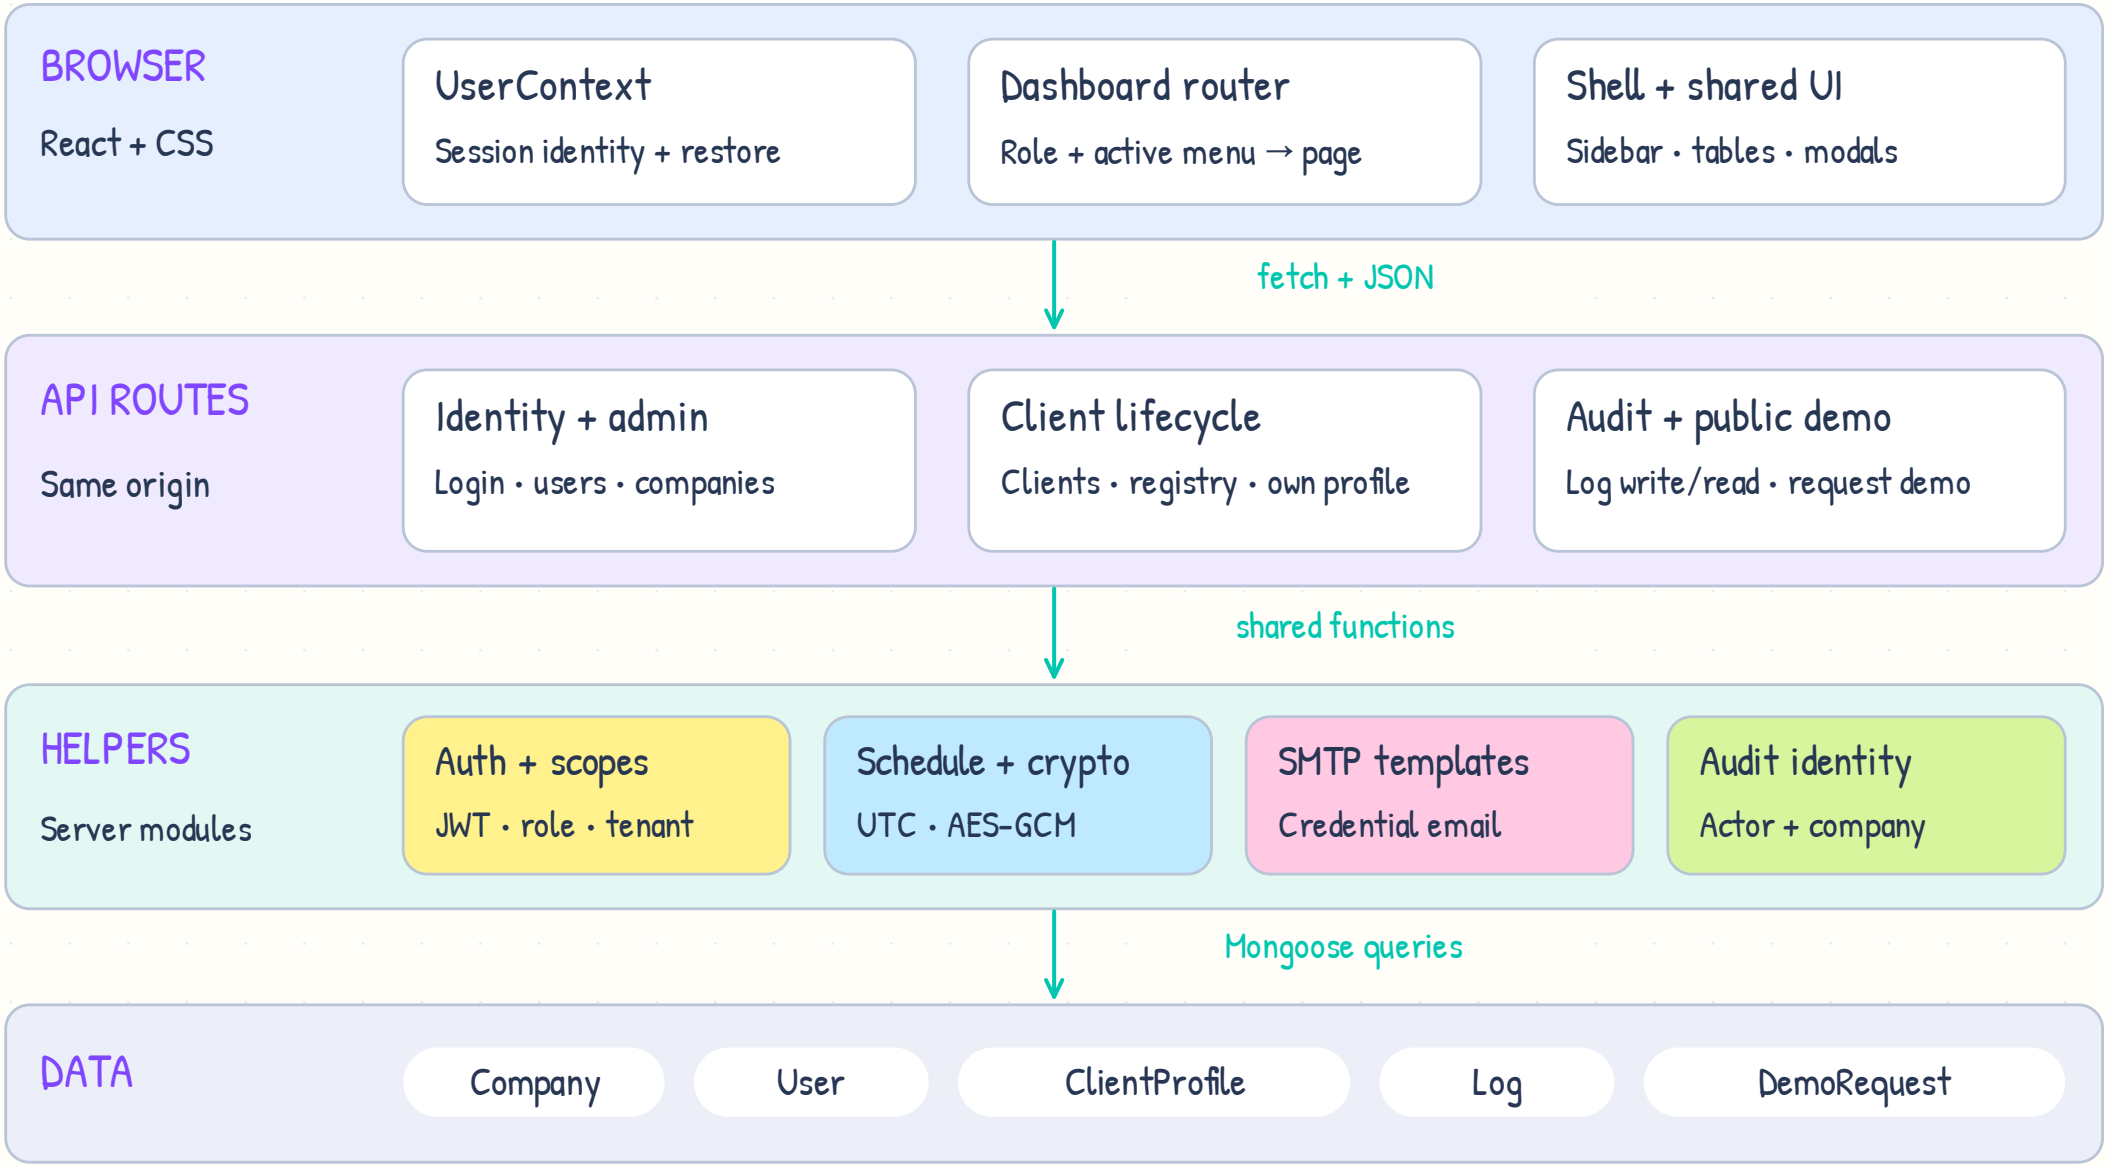

Four roles · one web application · one tenant-aware MongoDB data model

One codebase; deployment infrastructure and external scheduler configuration are outside this source model.

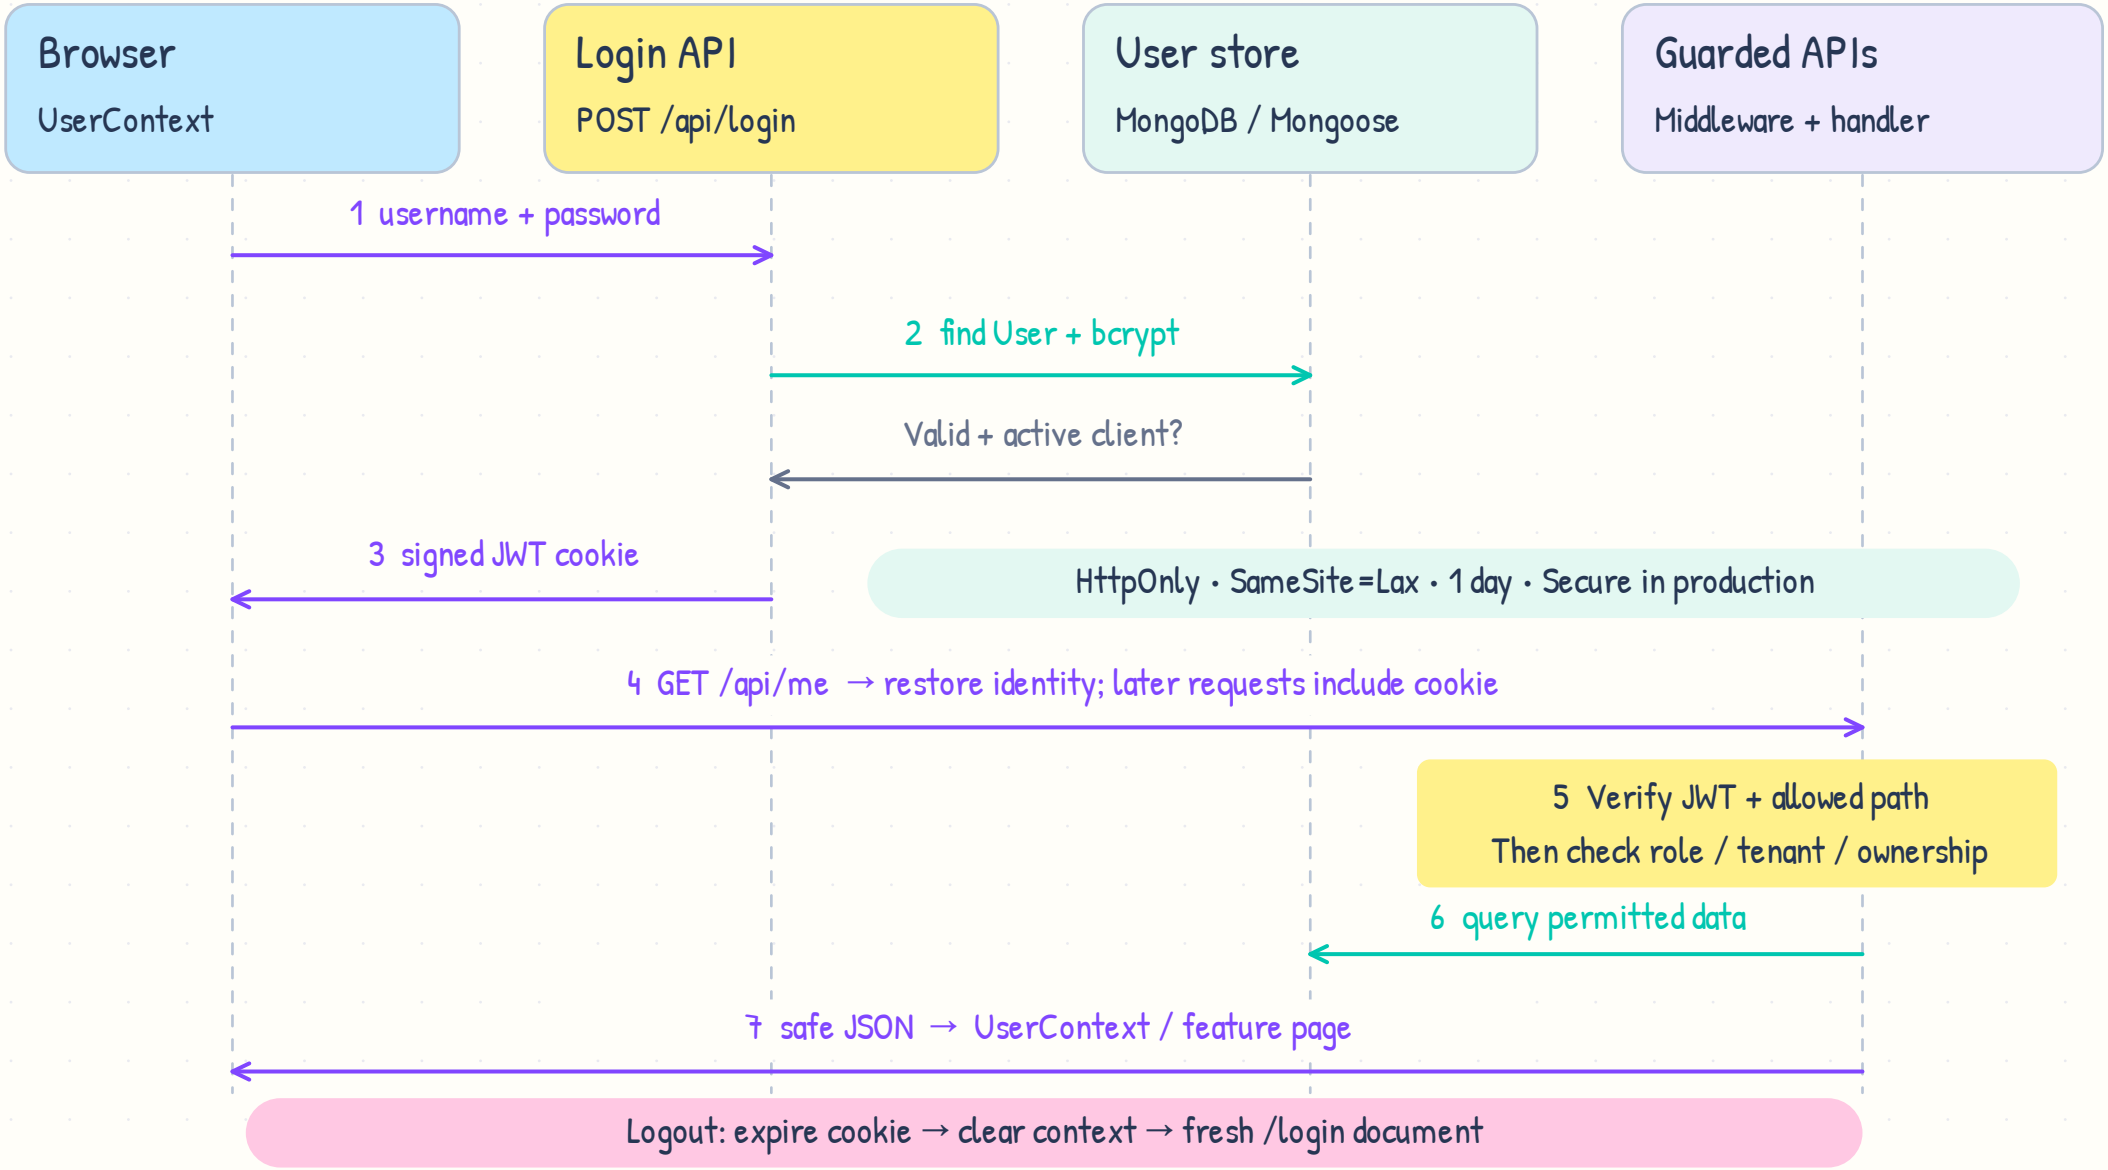

How the application is assembled

Layered runtime view · feature pages own their fetches · shared UI keeps the dashboard consistent

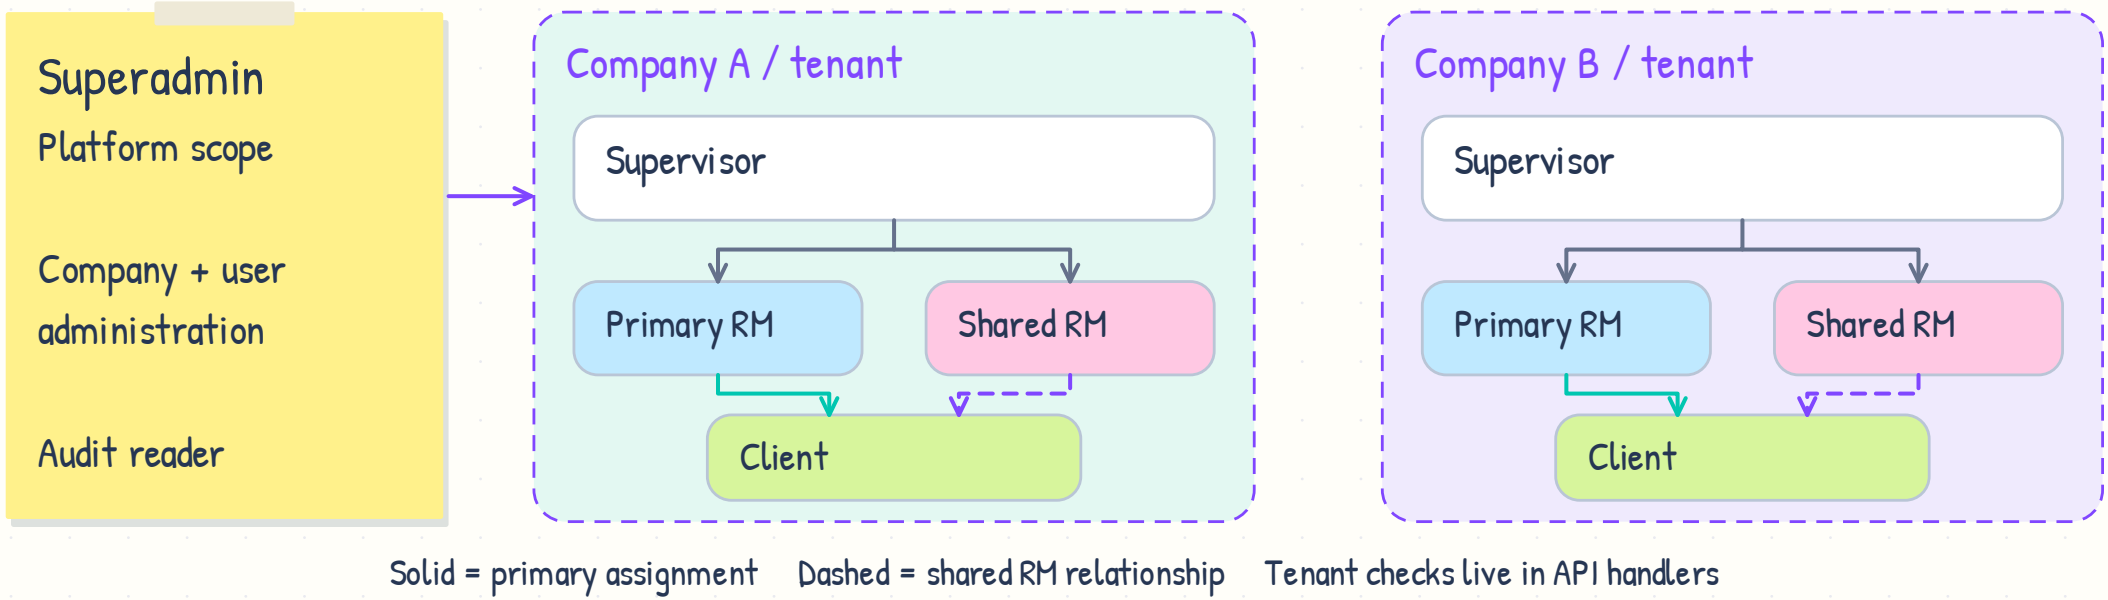

A session from login to protected data

JWT cookie flow · bcrypt password comparison · middleware and handler checks

Who can act, and inside which boundary?

Core workflow access model · shared database · companyId and actor relationships define scope

Solid = primary assignment Dashed = shared RM relationship Tenant checks live in API handlers

Actor	Data scope	Core actions / surfaces
Superadmin	Platform / all companies	Companies · supervisors · users · audit logs
Supervisor	Own company	RMs · clients · approve / review · assign / share
RM	Assigned + shared clients	Register · schedule · status; delete primary only
Client	Own profile	Read onboarding · profile; form save is pending

From routes to helpers to documents

Dependency map · each route combines its guards, business helpers and Mongoose models
